

Lederberg, E. M. Equivalence of the Mal<sub>1</sub> and Lp<sub>2</sub> loci in E. coli K-12.

Independent descriptions have been made of a locus, Mal<sub>1</sub>, controlling maltose fermentation and another, Lp<sub>2</sub>,

determining the susceptibility to the virulent lambda mutant, lambda-2. Both were known to be linked to S (streptomycin) and usually hemizygous in otherwise heterozygous diploids. Recent evidence supports the hypothesis that these diverse phenotypes are controlled at a single locus with apparently pleiotropic effects:

(1) existing stocks were found as either of two alternatives, Mal<sub>1</sub><sup>-</sup> and Lp<sub>2</sub><sup>r</sup> or as Mal<sub>1</sub><sup>+</sup> and Lp<sub>2</sub><sup>s</sup>.

(2) failure to obtain Mal<sub>1</sub><sup>+</sup>Lp<sub>2</sub><sup>r</sup> and Mal<sub>1</sub><sup>-</sup>Lp<sub>2</sub><sup>s</sup> crossover recombinants in large scale progeny tests when these stock cultures were crossed.

(3) Mal<sub>1</sub><sup>+</sup> reversions isolated as papillae from Mal<sub>1</sub><sup>-</sup>Lp<sub>2</sub><sup>r</sup> colonies on EMS maltose proved to be Lp<sub>2</sub><sup>s</sup>. From the latter Mal<sub>1</sub><sup>-</sup>Lp<sub>2</sub><sup>r</sup> reappeared among the resistant survivors after selection with lambda-2. This mutation cycle has been repeated several times and in several stocks.

Exceptional Mal<sub>1</sub><sup>+</sup> but lambda-2 resistant isolates which have also occurred have so far proved to be independent, nonallelic mutants at least one other locus, Lp<sub>1</sub>. This is not located in the S region according to both the linkage and the heterozygosity vs hemizygosity criteria. Several of our older diploid stocks are now known to be segregating for both Lp<sub>2</sub><sup>r</sup> Mal<sub>1</sub><sup>-</sup> and Lp<sub>1</sub><sup>r</sup>. Other types, possibly alleles of (Mal<sub>1</sub> Lp<sub>2</sub>) still under investigation include: 1) a mutable type giving heavily papillate colonies on EMS maltose; 2) an intermediate maltose fermenter which gives an "intermediate" resistance to lambda-2; and 3) a temperature-sensitive variant identical with (Mal<sub>1</sub><sup>+</sup>Lp<sub>2</sub><sup>s</sup>) at 37° and with (Mal<sub>1</sub><sup>-</sup>Lp<sub>2</sub><sup>r</sup>) at 37°.

Several Mal<sub>1</sub><sup>-</sup> mutants genetically distinct from Mal<sub>1</sub><sup>-</sup> have also been isolated following exposure to UV. Their reaction to lambda-2 is unchanged. All of them, including Mal<sub>1</sub><sup>-</sup>, are competent glucose fermenters at 37°. Resistance to lambda-2 can be selected on lambda-6 (kindly sent by Dr. J. J. Weigle) and on p-14, (the sewage phage previously described) as well as on lambda-2. The first of these attacks only Lp<sub>1</sub><sup>s</sup> bacteria (lambda-1 sensitive) while the latter attack Lp<sub>1</sub><sup>+</sup> and Lp<sub>1</sub><sup>r</sup> as well.

A preliminary attempt to link the fermentation and phage effects of the (Mal<sub>1</sub> Lp<sub>2</sub>) locus by assuming that amylose might serve as a receptor for lambda-2 was negative. Samples of starch ("waxy", soluble, or dextrin) had no demonstrable effect on blocking the adsorption of lambda-2.

Despite frequent purification, stock cultures of W-1 and its Mal<sub>1</sub><sup>-</sup> derivatives (notably W-1177 and W-1317) often contain Mal<sub>1</sub><sup>+</sup> components. If data on the Mal<sub>1</sub><sup>+</sup>/- segregation are desired from a cross, the purity of each parent should be verified.

What should this locus be called? Although the Mal<sub>1</sub> notation has priority, we have adopted the temporary expedient, (Mal<sub>1</sub> Lp<sub>2</sub>).--Department of Genetics, University of Wisconsin. Madison, Wisconsin.
